Recall that we may approximate a function of two variables, $z=f(x, y)$ using a tangent plane approximation. Namely, we may approximate $f(x, y)$ at points $(x, y)$ that are near a point $\left(x_{0}, y_{0}\right)$ using

$$
\begin{equation*}
f(x, y) \approx f\left(x_{0}, y_{0}\right)+f_{x}\left(x_{0}, y_{0}\right) \Delta x+f_{y}\left(x_{0}, y_{0}\right) \Delta y \tag{1}
\end{equation*}
$$

where $\quad \Delta x=x-x_{0} \quad$ and $\quad \Delta y=y-y_{0}$.
This is especially important when we need to approximate a function that is given by tabulated data. In other words, when we do not have a formula for the function.

EXAMPLE: Suppose we have the apparent temperature $I$ (in ${ }^{\circ} \mathrm{F}$ ) given in tabulated form as a function of the actual temperature $T$ (in ${ }^{\circ} \mathrm{F}$ ) and the relative humidity $H$.

|  | $\%$ Humidity, $H$ |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | 60 | 65 | $\mathbf{7 0}$ | 75 | 80 |
| 92 | 105 | 108 | 112 | 115 | 119 |
|  | $T$ |  |  |  |  |
| 94 | 111 | 114 | $\mathbf{1 1 8}$ | 122 | 127 |
| $\mathbf{9 6}$ | 116 | $\mathbf{1 2 1}$ | $\mathbf{1 2 5}$ | $\mathbf{1 3 0}$ | 135 |
| 98 | 123 | 127 | $\mathbf{1 3 3}$ | 138 | 144 |
| 100 | 129 | 135 | 141 | 147 | 154 |

For example, when the actual temperature is $96^{\circ} \mathrm{F}$ and the humidity is $70 \%$, then the apparent temperature is

$$
I(96,70)=125^{\circ} \mathrm{F} .
$$

Use linear approximation (tangent plane approximation) to approximate the apparent temperature $I$ when the actual temperature is $97^{\circ} \mathrm{F}$ and the humidity is $72 \%$.

From Eq. (1), we may approximate this by

$$
\begin{equation*}
I(97,72) \approx I(96,70)+I_{T}(96,70) \Delta T+I_{H}(96,70) \Delta H \tag{2}
\end{equation*}
$$

Here,

$$
\begin{aligned}
\Delta T & =97-96=+1 \\
\Delta H & =72-70=+2
\end{aligned}
$$

We also need to approximate the partial derivatives $I_{T}(96,70)$ and $I_{H}(96,70)$.
(next page...)

To approximate the partial derivatives $I_{T}(96,70)$ and $I_{H}(96,70)$.

|  | $H$ |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  |  | 65 | $\mathbf{7 0}$ | 75 |
| $T$ | $\mathbf{9 4}$ | 114 | $\mathbf{1 1 8}$ | 122 |
|  | $\mathbf{9 6}$ | $\mathbf{1 2 1}$ | 125 | $\mathbf{1 3 0}$ |
|  | 98 | 127 | $\mathbf{1 3 3}$ | 138 |

1. $I_{T}(96,70)=\frac{\partial I}{\partial T}(96,70)$ :

This is the partial derivative of $I$ wrt $T$, so $T$ varies and $H$ acts as a constant. So we use only numbers from the column $H=70$. We'll approximate this derivative by calculating the slope between points $\left(T_{1}, I_{1}\right)=(94,118)$ and $\left(T_{2}, I_{2}\right)=(98,133)$ :

$$
I_{T}(96,70)=\frac{\partial I}{\partial T}(96,70) \approx \frac{I_{2}-I_{1}}{T_{2}-T_{1}}=\frac{133-118}{98-94}=+3.75
$$

2. $I_{H}(96,70)=\frac{\partial I}{\partial H}(96,70)$ :

This is the partial derivative of $I$ wrt $H$, so $H$ varies and $T$ acts as a constant. So we use only numbers from the column $T=96$. We'll approximate this derivative by calculating the slope between points $\left(H_{1}, I_{1}\right)=(65,121)$ and $\left(H_{2}, I_{2}\right)=(75,130)$ :

$$
I_{H}(96,70)=\frac{\partial I}{\partial H}(96,70) \approx \frac{I_{2}-I_{1}}{H_{2}-H_{1}}=\frac{130-121}{75-65}=+0.9 .
$$

So by Eq. (2),

$$
\begin{aligned}
I(97,72) & \approx I(96,70)+I_{T}(96,70) \Delta T+I_{H}(96,70) \Delta H \\
& =125+(3.75)(1)+(0.9)(2) \\
& =130.55^{\circ} \mathrm{F} .
\end{aligned}
$$

CONCLUSION: When the actual temperature is $97^{\circ} \mathrm{F}$ and the humidity is $72 \%$, the apparent temperature is approximately $130.55^{\circ}$.

Note 1: Make sure the answer is reasonable. Based on the data in the table, the answer should be between the extreme values $125^{\circ} \mathrm{F}$ and $133^{\circ} \mathrm{F}$. Consequently, our result of $130.55^{\circ} \mathrm{F}$ is reasonable.

Note 2: This process really uses the tangent plane to function $I(T, H)$ at the point $(96,70)$ to approximate $I(97,72)$.
